

# Wiki Syntax

The pages are set to render everything inside as markdown by default using the CommonMark plugin. There is a way to specify native dokuwiki syntax as well though within the markdown. This means we can use markdown as a default but also add in any special plugin controls as well as a bonus.

To render native dokuwiki syntax we need to use a code fence block labeled with the dokuwiki name. Some controls / plugins don't require this depending on how they're written / the syntax used.

```
```dokuwiki
# Dokuwiki syntax goes here
```
```

Markdown is a more modern syntax currently used on github and also the same one used on the discourse mailing list website we're using.

## New lines

With markdown by default if you place one line of text directly below another one. Then both will be joined together without a newline but with a space such as this paragraph.

To force a newline add a double space at the end of the line. This will force the newline at the end of a line within a paragraph.

## Links

The normal syntax for markdown links is

```
[Plugins](.:plugins)
```

We can also use the dokuwiki syntax for links as well (which I admit is back to front compared to the above)

```
[[Plugins|. :plugins]]
```

## Fixme

One of the inbuilt controls that still works without any code fences is the Fixme label. If we write the

text **FIXME** in all capitals the end result is 

# Plugins

For the rest see the [plugins](#) section
